AGENDA

Model Domain and Hazard Module

Vulnerability and Model Validation

Model View of Risk

Key Use Cases

Q&A

SPEED
LIMIT
70

AIR Model Domain

Historical Ignitions ≥ 100 Acres (1992–2015)

Includes the Top Loss-Causing States:

California
Texas
Colorado
Arizona
Idaho
Washington
Oklahoma
Oregon
Utah
Montana
New Mexico
Nevada
Wyoming

Modeling the Conditions That Lead to Years Like 2017

AIR Worldwide Damage Survey (Tubbs, 2017)

- Fuels resulting from antecedent weather conditions
- Conditions during event
- Wildland Urban Interface (WUI)

Weather Patterns Drive Variability in Wildfire Activity

Temperature

Precipitation

Drought

AIR models weather patterns to
maintain natural variability

Wildfire Activity Is Modeled on the Ecoprovince Level

Northern Rocky Mountain Forest-Steppe
• **Coniferous Forest**

Ecoprovinces identify regions with similar ecosystems, climate, and vegetation—key drivers for fire behavior

Wildfire Activity Is Modeled on the Ecoprovince Level

Prairie Parkland
• Subtropical Province

Ecoprovinces identify regions with similar ecosystems, climate, and vegetation—key drivers for fire behavior

Wildfire Activity Is Modeled on the Ecoprovince Level

- California Coastal Range Open Woodland-Shrub
- Coniferous Forest—Meadow Province

Ecoprovinces identify regions with similar ecosystems, climate, and vegetation—key drivers for fire behavior

Relationships Between Weather and Fire Activity Are Complex and Vary Spatially

Fine Fuels

Fire behavior is correlated to the drought conditions during the **growing** season

Wet Growing Season = \uparrow Fire Activity

Dry Growing Season = \downarrow Fire Activity

Coarse Fuels

Fire behavior is correlated to the drought conditions during the **fire** season

Wet Fire Season = \downarrow Fire Activity

Dry Fire Season = \uparrow Fire Activity

AIR's Physically-Based Model Realistically Captures Fire Spread Across a Landscape

Ember Creation Is the Primary Driver of Wildfire Spread in Urban Areas

- Embers are created as materials within the fire perimeter are thrown ahead of the main fire front
- Allows fires to cross roads, rivers, and other natural fire breaks
- Most structures are ignited as embers collect on and around them

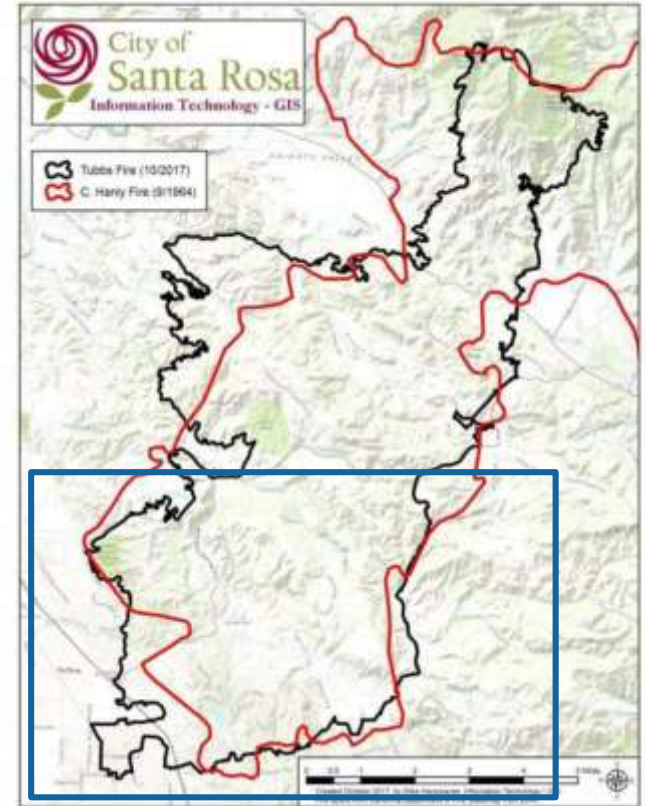

The WUI Is Critical to Understanding Wildfire Risk

Fountain Grove, Tubbs Fire Damage Survey, 2017

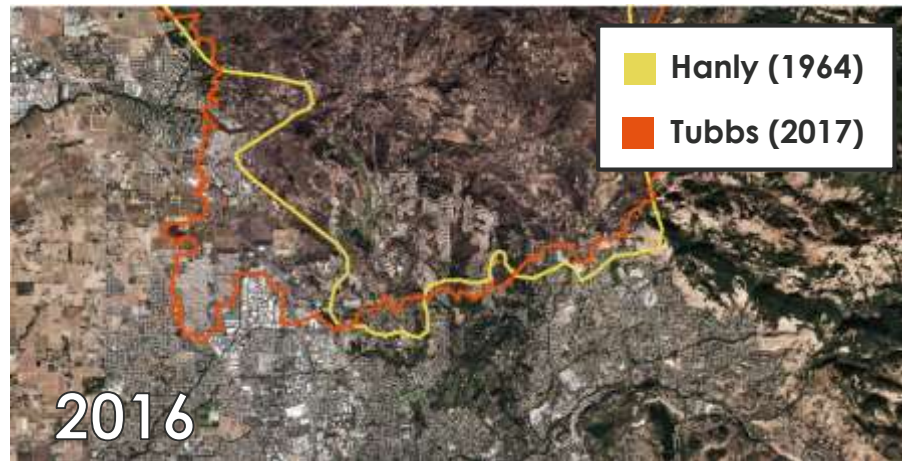

- Development intersects with undeveloped lands
- Largest economic losses from wildfire will occur in the WUI
 - One-third of U.S. households are located in the WUI
 - 4,000 acres of wildland are converted to WUI daily

Northern California Has Had the Hazard; However, Risk Is Growing

Verisk: FireLine®

FireLine provides a score, derived from an objective assessment of an exposure's propensity to burn in the event of a wildfire, based on the most current assessment of vegetative fuels, slope, and road access. Available in 13 U.S. states and two Canadian provinces*.

Simple Score, Multiple Uses

- UW eligibility
- Pricing
- Inspection
- Marketing
- Customizable

Leading Science and Technology

- Satellite/Remote sensing
- Machine learning
- Digital mapping

Granular and Reliable

- Property-specific scores
- Frequent updates reflect latest risk landscape
- Most extensive validation with post-wildfire data

Multiple Delivery Options

- Geographic information systems (GIS)
- On-line (ISO Passport® system and API)
- LOCATION® (database)
- ProMetrix®
- Touchstone®

*US - AZ, CA, CO, ID, MT, NV, NM, OK, OR, TX, UT, WA, and WY; Canada - AB and BC
